IN CASE OF FIRE **UK**

1. Inform the telephone operator immediately.
2. Use emergency fire exits.
3. Do not panic and follow the instructions of the hotel management or the fire brigade.
4. Do not use the elevator in case of fire.

IN GEVAL VAN BRAND **NL**

1. Verwittig onmiddellijk de receptie.
2. Gebruik enkel de nooduitgangen.
3. Volg de instructies die u door het hotel personeel worden gegeven. **BLIJF KALM**
4. Gebruik nooit de lift.

EN CAS D'INCENDIE **F**

1. Prévenez immédiatement le standard.
2. N'utilisez que les sorties de secours.
3. Suivez les instructions données par le personnel. **GARDEZ VOTRE CALME**
4. N'empruntez en aucun cas les ascenseurs

BEI FEUERGEFAHR **D**

1. Informieren Sie bitte sofort die Telefonzentrale.
2. Verlassen Sie je nach Lage Ihres Zimmers die Etage über die Nottreppen.
3. Bewahren Sie Ruhe und Umsicht und beachten Sie bitte die Anweisungen des Hotelpersonals und der Feuerwehr.
4. Aufzug im Brandfall nicht benutzen.

Rationale - in a nutshell

IN THEORY: CONSENSUS

- Antibiotic resistance is a major global threat
- Inappropriate prescribing => resistance
- A significant portion of antibiotic prescriptions in primary for respiratory tract infections are not appropriate
- CRP POCT and complementary strategies can help, when used properly

IN PRACTICE: LACK OF ACTION

- More than enough research on the subject
- Not enough practical action => opportunity to improve antibiotic stewardship
- New medicines will not help without behavior change, as resistance will be rebuilt

Outline

- Welcome – Dr Oliver Van Hecke

THE BIGGER PICTURE

Conference Aim

HOW WE WILL ACHIEVE THE OBJECTIVE

Conference Scope

Share **'European guidance'** to enable improved practice with the relevant stakeholders

Co-create regional implementation plans with key stakeholders to enable the approach to the European guidance

Support the execution of country-level action plans, that will positively **affect the desired behavioral change**

CONSENSUS STATEMENTS

CONSENSUS STATEMENT 1:

Antimicrobial resistance is a global threat that must urgently be addressed.

CONSENSUS STATEMENT 2:

Antibiotic overprescribing for respiratory tract infections in primary care is a significant contributor to rising antimicrobial resistance.

CONSENSUS STATEMENT 3:

C-reactive protein point of care testing (CRP POCT) is an established tool that is proven to effectively and safely reduce overprescribing of antibiotics for lower respiratory tract infections (LRTIs) in adults presenting at primary care.

CONSENSUS STATEMENT 4:

To safely reduce antibiotic prescribing in primary care for patients presenting with respiratory illness, a broader application of CRP POCT globally is recommended.

CONSENSUS STATEMENT 5:

An effective implementation, combining CRP POCT together with evidence-based complementary strategies, can increase the contribution to more appropriate antibiotic prescribing.

CONSENSUS STATEMENT 6:

In the ambulatory care of febrile children presenting with symptoms of respiratory illness, CRP POCT can be useful to guide decisions regarding antibiotic prescribing and hospital referrals.

CONSENSUS STATEMENT 7:

The use of CRP POCT for the management of patients presenting symptoms of LRTIs in primary care can be economically viable in several contexts.

Agenda Overview

MORNING PROGRAM: PRESENTATION OF THE 'EUROPEAN GUIDANCE'

- Share the expert group's consensus on the use of CRP POCT and complementary strategies
- Understand how to address over-prescription for respiratory illness in primary care

AFTERNOON PROGRAM: ACTION PLAN CO-CREATION WORKSHOPS

- Split into break-out groups per country for co-creation of action plans
- Draft a national action plan per country

What is Antimicrobial Resistance?

- **Antimicrobial Resistance (AMR)** occurs when bacteria, viruses, fungi and parasites do not respond to medicines making infections harder to treat and increasing the risk of disease spread, severe illness and death.
- WHO has declared that AMR is one of the top 10 global public health threats facing humanity

Impact of Antimicrobial Resistance

Attributable deaths and disability-adjusted life-years caused by infections with antibiotic-resistant bacteria in the EU and the European Economic Area in 2015: a population-level modelling analysis

Causes of Antimicrobial Resistance

A systematic review and meta-analysis of the effects of antibiotic consumption on antibiotic resistance

Brian G Bell¹, Francois Schellevis^{2,3}, Ellen Stobberingh⁴, Herman Goossens⁵ and Mike Pringle¹

Bell *et al. BMC Infectious Diseases* 2014, **14**:13
<http://www.biomedcentral.com/1471-2334/14/13>

Using a large set of studies we found that **antibiotic consumption is associated with the development of antibiotic resistance.**

A subsequent meta-analysis, with a subsample of the studies, generated several significant predictors. **Countries in southern Europe produced a stronger link between consumption and resistance than other regions so efforts at reducing antibiotic consumption may need to be strengthened in this area.** Increased consumption of antibiotics may not only produce greater resistance at the individual patient level but may also produce greater resistance at the community, country, and regional levels, which can harm individual patients.

THE IMPORTANCE OF ANTIBIOTIC STEWARDSHIP IN PRIMARY CARE

 CrossMark

A reservoir of 'historical' antibiotic resistance genes in remote pristine Antarctic soils

Marc W. Van Goethem^{1†}, Rian Pierneef^{2†}, Oliver K. I. Bezuidt¹, Yves Van De Peer^{1,3,4,5}, Don A. Cowan¹ and Thulani P. Makhalanyane^{1†} 

Abstract

Background: Soil bacteria naturally produce antibiotics as a competitive mechanism, with a concomitant evolution, and exchange by horizontal gene transfer, of a range of antibiotic resistance mechanisms. Surveys of bacterial resistance elements in edaphic systems have originated primarily from human-impacted environments, with relatively little information from remote and pristine environments, where the resistome may comprise the ancestral gene diversity.

Methods: We used shotgun metagenomics to assess antibiotic resistance gene (ARG) distribution in 17 pristine and remote Antarctic surface soils within the undisturbed Mackay Glacier region. We also interrogated the phylogenetic placement of ARGs compared to environmental ARG sequences and tested for the presence of horizontal gene transfer elements flanking ARGs.

Results: In total, 177 naturally occurring ARGs were identified, most of which encoded single or multi-drug efflux pumps. Resistance mechanisms for the inactivation of aminoglycosides, chloramphenicol and β -lactam antibiotics were also common. Gram-negative bacteria harboured most ARGs (71%), with fewer genes from Gram-positive *Actinobacteria* and *Bacilli* (*Firmicutes*) (9%), reflecting the taxonomic composition of the soils. Strikingly, the abundance of ARGs per sample had a strong, negative correlation with species richness ($r = -0.49, P < 0.05$). This result, coupled with a lack of mobile genetic elements flanking ARGs, suggests that these genes are ancient acquisitions of horizontal transfer events.

Conclusions: ARGs in these remote and uncontaminated soils most likely represent functional efficient historical genes that have since been vertically inherited over generations. The historical ARGs in these pristine environments carry a strong phylogenetic signal and form a monophyletic group relative to ARGs from other similar environments.

Keywords: Antibiotic resistance genes, Soil resistome, Antarctica, Metagenomics

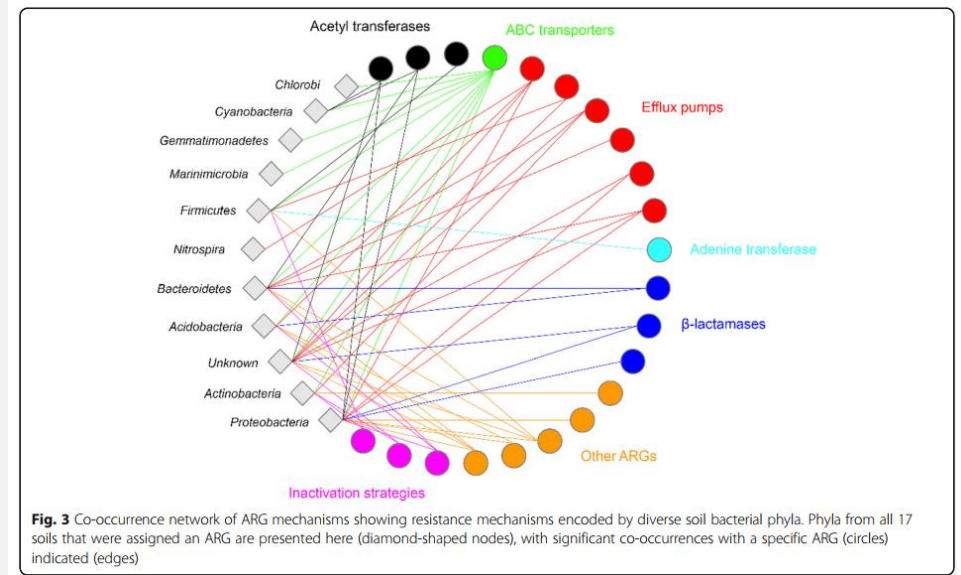

THE IMPORTANCE OF ANTIBIOTIC STEWARDSHIP IN PRIMARY CARE

Antibiotic resistance is often already present in nature, selective pressure with overuse of antibiotics greatly augment the diffusion

Table 2 ARG families found exclusively in a single community

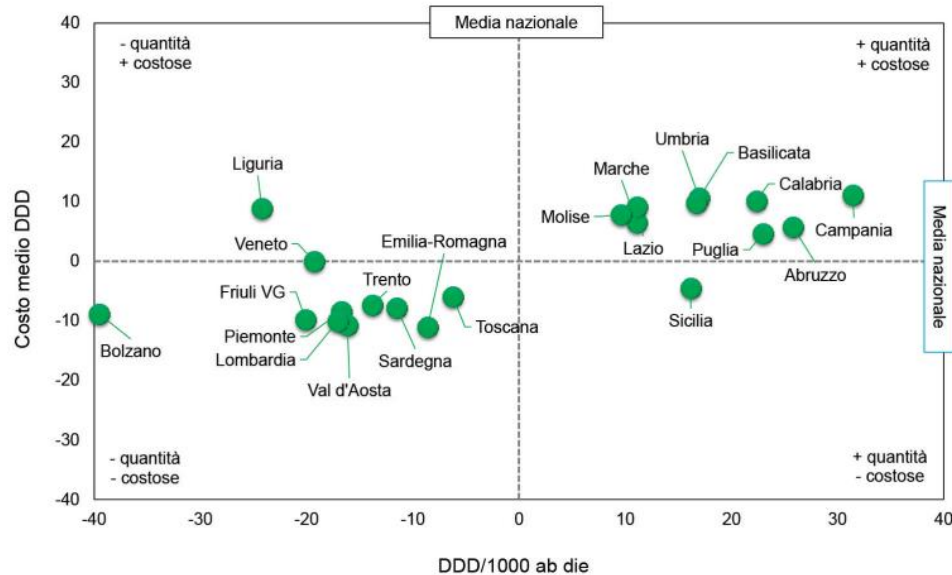

Sample site	ARG family description
MS4-1	Multidrug efflux pump
MGM-3	Dihydrofolate reductase, which cannot be inhibited by trimethoprim
MS1-1	Tet35 is a tetracycline efflux pump found in the Gram-negative <i>Vibrio</i> and <i>Stenotrophomonas</i> . Unrelated to other tet resistance genes
TG5-1	Aminoglycoside 6-N-acetyltransferase, which modifies aminoglycosides by acetylation
CN-4	Adenine transferase/methyltransferase, conferring resistance to erythromycin/kasugamycin
	Mutation frequency decline (Mfd) protein

Figure 3.1 Total antibiotic consumption by setting, expressed as DDDs per 1,000 inhabitants per day, England, 2017 to 2021

Objectives: To analyse antibiotic prescribing behaviour in English primary care with particular regard to which antibiotics are prescribed and for which conditions.

Methods: Primary care data from 2013–15 recorded in The Health Improvement Network (THIN) database were analysed. Records with a prescription for systemic antibiotics were extracted and linked to co-occurring diagnostic codes, which were used to attribute prescriptions to clinical conditions. We further assessed which antibiotic classes were prescribed and which conditions resulted in the greatest share of prescribing.

Results: The prescribing rate varied considerably among participating practices, with a median of 626 prescriptions/1000 patients (IQR 543–699). In total, 69% of antibiotic prescriptions ($n = 3\,156\,507$) could be linked to a body system and/or clinical condition. Of these prescriptions, 46% were linked to conditions of the respiratory tract, including ear, nose and throat (RT/ENT); leading conditions within this group were cough symptoms (22.7%), lower respiratory tract infection (RTI) (17.9%), sore throat (16.7%) and upper RTI (14.5%). After RT/ENT infections, infections of the urogenital tract (22.7% of prescriptions linked to a condition) and skin/wounds (16.4%) accounted for the greatest share of prescribing. Penicillins accounted for 50% of all prescriptions, followed by macrolides (13%), tetracyclines (12%) and trimethoprim (11%).

Conclusions: The majority of antibiotic prescriptions in English primary care were for infections of the respiratory and urinary tracts. However, in almost one-third of all prescriptions no clinical justification was documented. Antibiotic prescribing rates varied substantially between practices, suggesting that there is potential to reduce prescribing in at least some practices.

Respiratory tract infections (RTIs) in primary care: narrative review of C reactive protein (CRP) point-of-care testing (POCT) and antibacterial use in patients who present with symptoms of RTI

Jonathan Cooke^{1,2}, Carl Llor,³ Rogier Hopstaken,⁴ Matthew Dryden,⁵ Christopher Butler⁶

The influence of biomarkers on antimicrobial prescribing rates in patients presenting in primary care with symptoms of RTI

A 2015 survey of countries that employed CRP POCT as a diagnostic and/or prognostic tool in general practice showed those countries that used CRP POCT to some or a wide extent were: Finland, Netherlands, Denmark, Norway, Sweden, Germany, Czech Republic, Hungary, Austria, Slovenia, Latvia and Estonia.^{33 34} Interestingly, these countries are the lowest 12 prescribers of antibacterials in the latest ESAC survey (figure 1).³⁵ We have sought to review the evidence for the use of point-of-care (POC) biomarkers in reducing antimicrobial prescribing in primary care by prescribers who see patients presenting with symptoms of RTI. We felt that an update of our 2016

Conclusions

- Antibiotic resistance (AMR) is one of the greatest threats to global health and it is accelerated mainly by the misuse and abuse of antibiotics.
- The phenomenon of AMR is at-least partially reversible with a wise use of antibiotics.
- An integrated strategy can reduce the rate of inappropriate prescribing of antibiotics.
- Among the different approaches, the use of rapid test is one of the most promising.
